

Challenges in the Diagnosis of (Micro)Invasive Carcinoma

Adriana Corben, MD

Director Breast Pathology Fellowship

Overview

- Microinvasion
 - Helpful clues
 - Immunostains and pitfalls in interpretation
 - Clinical significance
- Invasive ca that mimics benign
- Invasive ca that mimics in situ
- Benign that mimics invasive ca

Microinvasion

2010 AJCC Staging Manual

- T1mi
- “Extension of cancer cells beyond the basement membrane...as an invasive ca with no focus measuring >1 mm”
- Not connected with CIS
- No need to subtype
- **!!** If multiple foci, should ***not*** be added together
- An attempt to quantify them should be included
- Prognosis is generally quite favorable
- Clinical impact of multifocality is not well understood

Always r/o microinvasion if...

- High grade or comedo-type DCIS
 - Other DCIS types can also have it
- Comedo-type or pleomorphic LCIS
- Extensive CIS
- Periductal lymphoid infiltrates
- Mucocele-like lesions

Useful lower-power field tools

- Irregularity of the contour of the nests/glands
- Retraction around the invasive nests
- Tumor nests/glands without a lobulocentric organization
- Chronic inflammation
- Reactive stroma
- Increased stromal cellularity
- DCIS: blurred edges of the duct wall due to tangential sectioning

Useful higher-power field tools

- Irregularity of the contour of the nests/glands
- No basement membrane (BM): tumor cells directly abut the stroma/adipose tissue
- No myoepithelial cells on H&E
- Retraction around the invasive nests

- **DCIS** with smooth contours (below)
- **Microinvasive carcinoma** with irregular contours (above)

IDC: absent lobular arrangement around benign

Invasion

•Stromal (periductal) chronic inflammation needs closer evaluation

•!! Useful: at final margins → levels!

Invasive lobular carcinoma with lymphocytes

HMW-CK

Reactive stroma and increased stromal cellularity

Microinvasive lobular simulates lymphocytes

DCIS: tangential sectioning of the duct wall will create a blurred edge

Helpful studies

- Definitive diagnosis is not always possible on H&E
- **!!** Most useful adjunctive studies:
 - IHC: at least **2** myoepithelial markers

Assessing invasion by IHC

- Invasive carcinoma:
 - *Lack* of both basement membrane and myoepithelial cells
- Benign and in situ lesions:
 - *Presence* of both basement membrane and myoepithelial cells

Myoepithelial cell markers

Marker	Sensitivity	Specificity
S-100	Good	Unacceptable
Actin	Good	Poor
SMMHC	Good	Excellent
Calponin	Excellent	Very good
HMW-CK	Very good	Poor

Adapted from Yaziji, et al. Adv Anat Pathol 2000, 7:100-109

Calponin

Calponin: easily overlooked microinvasive carcinoma

An **H&E** section paired with 2 myoepithelial cell markers is critical

MOST COMMONLY USED	USED	RARELY USED
CALPONIN	CK5/6	S100
SMMHC	CD10	
SMA	34B12	
p63		

p63

- p53 family
- Nuclei only
- High sensitivity
- High specificity
- No myofibroblast staining
- Positive in some DCIS and IDC (metaplastic)

Tubular adenosis

Calponin

Tubular adenosis

SMMHC

Invasive tubular ca with SMA positive myofibroblasts

Myofibroblast cross-reactivity of myoepithelial cell markers

SMA	+++
Calponin	++
SMMHC	+
p63	-

A HMW-CK paired with 2 myoepithelial cell markers is critical

Lobular carcinoma
cells invade the
interlobular
collagenous stroma

Multinucleated stromal giant cells

Cytokeratin

Clinical significance of microinvasion

- Studies in the past:
 - small numbers
 - varying definitions
 - varying degrees of tissue sampling
- No clear differences from pure DCIS
- Clinical significance is unclear

Single cells in the stroma: what do they mean?

De Mascarel, Cancer 2002; 94:2134

Axillary LN involvement and 10 yrs outcome

	#pts	%node+
DCIS	722	1.4%
DCIS + single cells in stroma	72	0

De Mascarel, Cancer, 2002

	DDFS	OS
DCIS	98%	96.5%
DCIS + single cells in stroma	97%	96.3%

Single cells in the stroma: what do they mean?

- **No evidence** that:
 - Is associated with axillary LN +
 - Has adverse clinical outcome
- In practice, we consider them **microinvasion**
- By using **AJCC definition** pts will likely have:
 - Very low rate of ALNM
 - Cure rate approaching 100% with good local treatment
- Goal: **identify** this subset of **pts**

Invasive Carcinoma that Mimics Benign

Useful clues

- Glandular disarray
- Irregular tubules/glands of variable size/shape/orientation
- Infiltration around benign
- Open glandular lumina
- Lack of BM and myoepithelium
- Stromal hypercellularity
- Stromal desmoplasia

IDC mimicking benign adenosis

SMMHC

Invasive ductal carcinoma surrounding DCIS

Invasive carcinoma within sclerosing adenosis

IDC mimics benign breast, but no BM and myoepithelium

Suspect ILC: Stromal hypercellularity and desmoplasia

**Invasive carcinoma
that mimics in situ**

Problematic patterns

- Nested invasion
- Blunt invasion
- Occlusive LVI

Clues for nested invasion

- Too confluent and/or haphazard distribution
- Large nests adjacent to completely normal lobules
- Irregularities in the contour of the nests
- Reactive stroma (if present)
- The following two pictures show how IDC can mimic DCIS

Clues for blunt invasion

- Common in solid papillary carcinoma and papillary carcinoma
- Too large nests
- Discontinuity along the periphery of the nests
- Fat, collagen, large vessels or benign glands entrapped

Large size of
the nests
raises
concern of
blunt
invasion

Case initially misdiagnosed as DCIS

SMA

p63

IDC

vs

DCIS

Calponin

Invasive Papillary Carcinoma

p63

Clues for occlusive LVI

- Buckshot distribution
- In arteries and veins
- Carcinoma associated with vascular bundle
- D2-40 + and p63 –
- **!!** Issue: foci near margins
- The next 2 pictures show occlusive LVI mimicking DCIS

D2-40

- Ab to human podoplanin
- Used to identify lymphatic vessels
- Less myofibroblast staining
- **!!** DCIS or LCIS with retraction could be misinterpreted as LVI (and viceversa)

Benign lesions that mimic invasive carcinoma

Sclerosing and pseudoinvasive lesions

- Radial scar/complex sclerosing lesion
- Sclerosing adenosis
- Involvement of benign lesions by CIS
- Microglandular adenosis (MGA)
- Multinucleated stromal giant cells
- Mucocele-like lesions
- Sclerosing papillary lesions

Radial Scar Nidus

Tubular Carcinoma

Radial Scar Nidus

DCIS

UDH

Sclerosing adenosis

ALH in sclerosing
adenosis

Invasive lobular
carcinoma

DCIS involving a sclerosing lesion

Calponin

MGA vs Tubular ca:

- Fibrotic stroma
- Uniform, round tubules
- No snouts
- Eosinophilic colloid-like secretion
- Prominent BM
- ER negative
- S100 positive
- **!!** Myoep negative

MGA reported associated with ca in up to 25% of cases

- *Rosenblum Am J Surg Pathol*
1986;10:237
- *James Am J Clin Pathol*
1993;100:507
- *Acs Am J Surg Pathol*
2003;27:1052
- *Resetkova Arch Pathol Lab*
Med 2003;127:77
- *Salarieh, Sneige Arch Pathol*
Lab Med 2007;131:1397

AMGA

MGA and Carcinoma

- Similar immunoprofile
 - ER -
 - Myoepi -
 - S100 +
- Overlapping genetic alterations
- Suggested transition as a non-obligate precursor

*Shin S, et al. Am J Surg Pathol
2009;33;496*

Recurrent issues with MGA

- Core biopsy
 - Difficult to recognize
 - Recommend excision
- Surgical specimen
 - MGA at margin → complete excision

Artifactual displacement

Artifactual displacement

- Epithelium confined to biopsy site
- Benign cytology with round and “shrunken” glands
- Benign primary lesion
- Myoepithelial cells may or may not be retained
 - More useful, if positive
 - p63 more specific

Summary

- Microinvasion
 - Helpful clues
 - Immunostains and pitfalls in interpretation
 - Clinical significance
- Invasive ca that mimics benign
- Invasive ca that mimics in situ
- Benign that mimics invasive ca
